50% of miscarriages in the first trimester are caused by chromosomal abnormalities.

After a miscarriage, it is important to identify the causes.

If you have suffered repeated miscarriages, you need to find out why, and how to prevent recurrences.

Miscarriages in the first trimester of pregnancy are common: 50% are caused by chromosomal abnormalities, and this increases to >60% in women undergoing assisted reproduction treatment.

Every cell of the human body contains 46 chromosomes arranged into 23 pairs. One copy comes from the father and another from the mother.

Chromosomal abnormalities, caused by an incorrect number of chromosomes or by loss or gain of chromosomal material, can result in miscarriage.

The POC (Products of Conception) test by Igenomix is an advanced analysis of fetal tissue using NGS technology that helps determine if the miscarriage was caused by a chromosomal abnormality.

Benefits of our POC test

- **Reliable**: Results are obtained in 99% of cases, versus 58% in conventional tests.
- **Fast**: Results in 10 working days, versus 1 month for conventional tests.
- **Rules out maternal contamination**: a blood sample from the mother verifies that the analyzed material is fetal in origin.

The POC test provides genetic information that enables appropriate reproductive counselling to help you plan any future pregnancies.

Test procedure

1. Complete test request and consent forms
2. Sample is collected
3. Maternal blood draw
4. Send to Igenomix
5. DNA sequencing (NGS)
6. Results available in 10 working days
